

14 Nutrient Requirement Tables

Requirements for rumen degradable protein (RDP), rumen undegradable protein (RUP), and total protein are dependent on animal factors, the concentration of available energy in the diet, and dry matter intake. The dietary requirement for minerals depends on animal factors and the bioavailability of the minerals which differs among feedstuffs and diets. Tables of nutrient requirements are included to provide users with general guidelines and to illustrate how dietary factors influence requirements of some nutrients. The computer model uses animal and dietary factors to estimate requirements and will produce the most accurate estimates of requirements for specific situations and specific diet formulations. Users are strongly encouraged to use model-generated requirements.

LACTATING COWS

Tables 14-1 through 14-6 show RDP, RUP, and total crude protein (CP) requirements for small and large breed lactating cows at different production levels as generated by the computer model. These tables also illustrate the effect of dietary energy concentration (Tables 14-2 vs. 14-3 and 14-5 vs. 14-6) and the effect of intake (Tables 14-1 vs. 14-2 and 14-4 vs. 14-5) on protein requirements. Tables 14-7 through 14-9 provide estimates of nutrient requirements of lactating (early and mid) and dry cows. These tables were also generated using the computer model, but the subcommittee has included its recommendations for certain nutrients that require special consideration, when using the model. Dietary requirements for minerals shown in Tables 14-7 through 14-9 are applicable only to the diets included in the tables. Different diets, because of differences in bioavailability of minerals may yield different dietary requirements for minerals.

The values in the tables are the subcommittee's best estimates of requirements when cattle are fed specific dietary formulations under nonstressful environmental

conditions. These tables (Tables 14-1 through 14-16) are intended as guides, and readers are encouraged to pay careful attention to footnotes in the tables. The computer model allows great flexibility in accounting for many dietary, environmental, and management factors that affect animal performance in contrast to the static numbers presented in tables.

HEIFERS

The equations outlined in Chapter 16 were used to develop tables containing guidelines for the nutrient requirements of dairy replacement heifers (Tables 14-12 through 14-16). At a predicted DMI, the TDN concentration needed to meet the requirements for maintenance and gain were determined. The requirements obtained with the computer program may differ slightly from those in Tables 14-12 through 14-15 because the model-predicted supply of nutrients affects the calculation of some dietary requirements. These differences are due to variation in RUP intestinal digestibility, predicted diet TDN, and mineral bioavailabilities as described below. These tables are guidelines only and the NRC computer program should be used to evaluate the nutritional adequacy of specific diets. These requirement tables were calculated to approximate the requirements obtained with the computer program when heifers are fed a typical diet at the model-predicted dry matter intake, using the following assumptions.

1. The TDN used is the TDN discounted to account for depression in digestibility at intakes above maintenance.
2. DE (Mcal) was assumed to equal $4.409 \times \text{TDN} (\text{kg})$. In the model, this value varies slightly among diets.
3. An RUP intestinal digestibility of 67 percent was assumed. This value ranges from 60 percent for diets based entirely on very mature forages fed to heifers with low requirements to approximately 75 percent for diets typi-

cally fed to animals with high requirements in which much of the supplemental protein comes from concentrates. Thus, the dietary RUP needed to meet the requirement for metabolizable protein should be increased approximately 10 percent if most of the diet consists of mature forages and can be decreased 10 percent if the diet is based on combinations of forages and concentrates typically fed to animals with high requirements.

4. Body weights and daily gains in the table are expressed on a full body weight basis although, in the model, they are converted to shrunk (96 percent of BW) and empty body (89.1 percent of SBW) weights to compute requirements.

5. It is assumed that there is no stress due to weather and that the body condition score of the animal is 3.

6. Net requirements were converted to dietary requirements by assuming an average bioavailability of 40 percent for calcium and 67 percent for phosphorus. These values were obtained by formulating diets for target ADG across a range of body weights. Across these diets, the bioavailability of phosphorus was relatively constant (near 67 percent), but calcium bioavailability ranged from 32 percent for diets with no supplemental calcium to 41 percent for diets supplemented with calcium carbonate.

7. For pregnant heifers, body weight (BW) includes the conceptus weight (kg) shown, which is computed using the equation in the model assuming that birth weight equals 6.275 percent of mature weight.

8. For pregnant heifers, reported daily gains are heifer ADG with and without conceptus (ADG in parentheses include the conceptus gain (kg/d), which is computed with the model equation). The requirements for pregnancy are included in the total requirements.

The body weights and daily gains in the tables were selected to reflect likely values for heifers in both typical and accelerated heifer rearing programs. Some of the trends that are apparent in the tables include:

1. The effects of mature weight and current body weight on net energy and protein requirements are evident in the

tables. Animals that have higher rates of gain have higher energy and protein requirements for growth and, as the animal matures, the amount of energy required for a particular daily gain increases. However, RUP and RDP requirements are more complicated. The factors affecting these calculations are: If two heifers have similar current body weights, but different mature weights, the required TDN concentration of the diet is higher for animals with the smaller mature weight because the NE_G requirement is higher. The higher TDN permits the growth of more microbes provided that adequate RDP is available. Thus, the RDP requirements are higher in the animals with the smaller mature size.

2. Stage of growth of the heifer also affects CP and RUP requirements. When mature size increases, the physiological age at which an animal reaches a specific weight is reduced. The result is that the efficiency with which protein is used for growth increases. The increase in the amount of net protein required for growth by animals with larger mature sizes at a set body weight and ADG may be offset by the higher efficiency of use of the absorbed protein.

3. As a result of these two factors, RUP and CP required may actually be lower for animals with a larger mature weight at a given body weight and ADG than for animals with smaller mature weights. These interactions are illustrated below for a body weight of 300 kg and an ADG of 0.8 kg/day for both mature sizes.

Mature weight, kg	450	650
% of mature weight	67	41
NE _G required, Mcal/day	3.13	2.38
DMI, kg/d	7.1	7.1
Diet TDN, %	67.7	63.4
Net protein required, g/d	114	136
Equivalent body weight, kg	319	221
Efficiency of MP use for NP, %	47.1	58.2
MP required, g/d	524	525
MP from microbial protein, g/d	443	409
RDP required/g/d	736	685
RUP required, g/d	151	183
CP required, g/d	887	868

^aDiet used for this table consisted of 15% immature legume silage, 33% normal corn silage, 34% ground high moisture shelled corn, 12% soybean meal (48% crude protein), 2.5% tallow, 1.5% menhaden fish meal, and 2% mineral and vitamin mix. Requirements are dependent upon the diet fed. Requirements shown do not include nutrients needed for live weight change. Live weight change is based on assumed NE_L intake minus requirements. Requirements for RUP do not include protein provided by loss in body reserves or required for gain in body reserves. Requirement for total CP assumes RDP and RUP are met. Requirement for total CP will increase if RDP requirement is not met.

^aDiet used for this table consisted of 15% immature legume silage, 33% normal corn silage, 34% ground high moisture shelled corn, 12% soybean meal (48% crude protein), 2.5% tallow, 1.5% menhaden fish meal, and 2% mineral and vitamin mix. Requirements are dependent upon the diet fed. Requirements shown do not include nutrients needed for live weight change. Live weight change is based on assumed NE_L intake minus requirements. Requirements for RUP do not include protein provided by loss in body reserves or required for gain in body reserves. Requirement for total CP assumes RDP and RUP are met. Requirement for total CP will increase if RDP requirement is not met.

^a Recommended energy content of early lactation rations must be limited to prevent rumen acidosis. Cow must therefore be expected to utilize body reserves to meet energy needs at highest levels of milk production. See fiber and NFC restrictions.

^b Equivalent to crude protein requirement only if RDP and RUP are perfectly balanced.

^c These are the minimum fiber (or maximum NFC) concentrations needed to maintain rumen health and milk fat test (see Chapter 4).

^d Assumes that active transport of magnesium across the rumen wall is intact. High dietary potassium and excess non-protein nitrogen often interfere with Mg absorption. Under these conditions dietary Mg should be increased to 0.3%–0.35% (see Chapter 6).

^e Heat stress may increase the need for potassium (see Chapter 6).

^f High dietary molybdenum, sulfur, and iron can interfere with copper absorption increasing the requirement (see Chapter 6).

^g Diets high in goitrogenic substances increase the iodine requirement (see Chapter 6).

^h Diet composition is the same in all four cases of the Jersey cow producing 35 kg milk. Amount of dry matter consumed varies with days in milk and the use of predicted vs. actual dry matter intake in the model.

^aRecommended energy content of early lactation rations must be limited to prevent rumen acidosis. Cow must therefore be expected to utilize body reserves to meet energy and protein requirements of early lactation. See fiber and NFC restrictions.

^bIt will be nearly impossible to meet the metabolizable protein needs of the high producing fresh cow due to low dry matter intake and the difficulty formulating rations with such high RUP.

^cEquivalent to crude protein requirement only if RDP and RUP are perfectly balanced.

^dThese are the minimum fiber (or maximum NFC) concentrations needed to maintain rumen health and milk fat test (see Chapter 4).

^eAssumes that active transport of magnesium across the rumen wall is intact. High dietary potassium and excess non-protein nitrogen often interfere with Mg absorption. Under these conditions dietary Mg should be increased to 0.3%–0.35% (see Chapter 6).

^fHeat stress may increase the need for potassium (see Chapter 6).

^gHigh dietary molybdenum, sulfur, and iron can interfere with copper absorption increasing the requirement (see Chapter 6).

^hDiets high in goitrogenic substances increase the iodine requirement (see Chapter 6).

^aRUP corrected from model prediction to provide actual RUP requirement if diet had been formulated to meet RDP requirement. Protein in many cases will not be balanced for RDP before the metabolizable protein requirement of the dry cow is met. When this occurs the RUP requirement determined by the model increases to compensate for the lost microbial protein. When RDP is inadequate the energy derived from the diet may be less than predicted by model due to incomplete digestion as a result of reduced bacterial activity in the rumen.

^b% RUP + % RDP = Crude protein required only if ration is perfectly balanced for RDP and RUP. Rumen function may require that the crude protein content of the dry cow ration be 12%, despite the needs of the cow being met at lower CP levels.

^cThese are the minimum fiber (or maximum NFC) concentrations needed to maintain rumen health and milk fat test (see Chapter 4). Actual concentrations may need to be higher (or lower for NFC) depending on energy requirements of the cow. For transition and early lactation cows, diets should meet these minimum and maximum constraints and be formulated to contain 1.60 Mcal/kg of NE_L (see Chapter 9).

^dHigh dietary potassium and excess non-protein nitrogen can interfere with Mg absorption.

^eHigh dietary molybdenum, sulfur, and iron can interfere with copper absorption increasing the requirement (see text).

^fDiets high in goitrogenic substances increase the iodine requirement (see text).

272 Nutrient Requirements of Dairy Cattle

TABLE 14-10 Example Diet Incorporating Dietary Guidelines Suggested in Chapter 9 for Transitioning a Heifer (entering first lactation) During the Later Dry Period to Acclimate Her To the Lactating Ration and To Reduce Metabolic Disease

This animal must be entered into the model as a replacement heifer to accommodate growth requirements. Tissue requirements for a heifer (270 d pregnant, weighing 625 kg with conceptus, mature body weight of 680 kg, consuming 10.6 kg dry matter / day, gaining 300 g body weight plus 660 g conceptus weight each day, and a current body condition score of 3.3) and nutrient densities of an example ration that follows the recommendation guidelines.

^aEnergy increased to prepare rumen for lactation ration, promote feed intake, and reduce displaced abomasum after calving.

^bRUP corrected from model prediction to provide RUP requirement if diet can be formulated to meet RDP requirement.

^c% RUP + % RDP = Crude Protein Required only if ration is perfectly balanced for RDP and RUP.

^dProtein in most cases will not be balanced for RDP before the metabolizable protein requirement of the dry cow is met. When this occurs the RUP requirement determined by the model increases to compensate for the lost microbial protein. When RDP is inadequate the energy derived from the diet may be less than predicted by model due to incomplete digestion as a result of reduced bacterial activity in the rumen. In order to improve rumen digestion the recommendation is to exceed the cow's requirement for metabolizable protein to meet the RDP requirement of the rumen.

^eSuggested carbohydrate profile to reduce displacement of the abomasum.

^fUtilizing the DCAD concept to prevent milk fever, diet calcium does not have to be limited.

^gA level which will provide adequate phosphorus even on the day of calving when DMI is low.

^hA level which will allow passive absorption of magnesium across the rumen wall to maintain adequate blood magnesium concentration.

ⁱAdding anions to the ration to reduce hypocalcemia.

^jGoal would be to limit potassium to the requirement of the cow. Very difficult to achieve.

^kA level which will provide adequate vitamins even on the day of calving when DMI is low.

^lMonitoring urine pH can help titrate the correct DCAD of the ration.

^mMore palatable sources of anions than used in this example are available and would likely impair DMI less.

ME allowable ADG without conceptus of diet	0.82	0.87	0.86
ME allowable ADG with conceptus of diet	0.82	0.87	0.86
MP allowable ADG without conceptus of diet	0.76	1.09	1.30
MP allowable ADG with conceptus of diet	0.76	1.09	1.30

^aEquivalent to crude protein requirement only if RDP and RUP are perfectly balanced.

^bThese are the minimum fiber (or maximum NFC) concentrations needed to maintain rumen health (see Chapter 4). Actual concentrations may need to be higher (or lower for NFC) depending on energy requirements of the heifer.

^cAssumes that active transport of magnesium across the rumen wall is intact. High dietary potassium and excess non-protein nitrogen often interfere with Mg absorption. Under these conditions dietary Mg should be increased. (see Chapter 6).

^dHigh dietary Mo, sulfur, and Fe can interfere with Cu absorption increasing the requirement (see Chapter 6).

^eDiets high in goitrogenic substances increase the iodine requirement (see Chapter 6).

15

Nutrient Composition of Feeds

Data in Table 15-1 were compiled from commercial laboratories, literature data, *Nutrient Requirements of Beef Cattle* (National Research Council, 1996), and unpublished data provided by university researchers. When commercial laboratory data disagreed greatly with published data (>1.5 SD from the mean), the published data were used. The table includes means, standard deviations, and the number of samples (N) used to generate those statistics. Users should examine the standard deviation and N before using the mean value as an estimate of the nutritional content of a specific feed sample. Means derived from a large N will better reflect the total population. Means with a large standard deviation may represent the total population but may be a poor estimate for a specific sample.

All energy values in Table 15-1 were calculated from the mean nutrient data for each entry. Values for ME and NE_L assume the diet has 74 percent TDN. Neutral detergent insoluble crude protein (NDICP) and acid detergent insoluble crude protein (ADICP) are not used directly to formulate diets but are used to calculate energy. Ether extract values represent the total lipid content of a feed but is a poor index of the true fat content of many feeds. The concentration of fatty acids in a feed is a measure of the true fat content and should replace the ether extract assay (Sukhija and Palmquist, 1988). Ether extract values were retained in this edition because of the limited availability of fatty acid data for most feedstuffs. In some cases, data were used that were derived with different analytic techniques, especially neutral detergent fiber (NDF) because other data were not available (see section on Analytic Procedures in chapter 13). Lignin and ash concentrations are used only to estimate energy values and the majority of lignin values were determined using sulfuric acid acid detergent lignin (ADL). Fiber concentrations are not presented for animal-based feedstuffs because the values have little meaning. Concentrations of macro and trace minerals are included in the table; however, before using these values, examine the standard deviations. Soil concentrations of minerals are highly variable; geographic differ-

ences exist for the mineral concentrations of many feeds. For most trace minerals, the standard deviation is high. The use of mean values for copper, iron, manganese, selenium, and zinc is discouraged. Concentrations of molybdenum are provided only in reference to copper availability.

For a very limited number of entries, the concentrations of certain nutrients (NDICP, ADICP, and some minerals) were estimated. Values in the table with no N were estimated. Generally the estimates were from a larger population (e.g., the sulfur concentration for normal corn silage also was used for immature corn silage). For some hay crop forages, values for a specific maturity class were estimated from the *all samples* entries. For some forage classifications, estimates of NDICP and ADICP were calculated from the mean value as a percent of crude protein (CP) for the *all sample* entries and multiplying that value by the mean CP for the specific entry. Data for ground corn (dry and high moisture) was used for cracked dry and high moisture corn. Data for dry rolled sorghum was used for steam-flaked sorghum.

Common names were used to designate feeds. In contrast with previous editions, data for different species of cool season grasses (C-3) were combined into a single classification (Grasses, Cool Season). The classification was simplified because nutrient composition does not vary greatly among different species (Cherney et al., 1993). Similarly, common legumes (alfalfa, clover, trefoil) were combined into a single classification (Legumes, Forage). The standard maturity classifications were eliminated because data from commercial labs and published data often do not include specific maturity designations. Within the cool season grasses and forage legume categories entries were broken into low NDF, medium NDF, and high NDF. Typically less mature forages contain lower NDF concentrations, but growing conditions can alter that relationship. The NDF concentrations, included in each entry are in the table. Because of the widespread use of mixed legume and grass forages, entries were included for this type of forage. The difference in hemicellulose

concentrations between legumes and grasses was used to partition feeds into mostly (>70 percent) grass mixtures, mixtures with approximately equal amount grass and legume, and mostly (>70 percent) legume mixtures. Maturity classification for mixed forages was also based on NDF concentrations. Maturity of corn silage was estimated from dry matter content. Generally, as corn plants mature, dry matter increases (Wiersma et al., 1993).
